# Bubble sort method

Some one give us a vector of unsorted numbers  
We want to obtain the vector sorted in ascending order

- assign the *index* of the last element to check to be the end of vector
- start sweeping from the beginning of the vector
- Compare the 2 consequent elements till we reach the end of array
- if left one is larger we swap these 2 elements
- notice that at the end of the sweep the *index* of the last element to check holds the largest element
  - so next sweep does not have to be that long.
  - it is shorter by one element
  - i.e. the *index* of the last element to check should be decreased by 1
- start new sweep till the *index* of the last element to check  $> 1$

$x = [3, 1, 4, 5, 2]$

first sweep

$x = [\widehat{3}, 1, 4, 5, 2]$  swap

$x = [1, \widehat{3}, 4, 5, 2]$  no swap

$x = [1, 3, \widehat{4}, 5, 2]$  no swap

$x = [1, 3, 4, \widehat{5}, 2]$  no swap

$x = [1, 3, 4, 5, \widehat{2}]$  swap

$x = [1, 3, 4, 2, \widehat{5}]$  sweep done

new sweep

$x = [1, \widehat{3}, 4, 2, 5]$  no swap

$x = [1, 3, \widehat{4}, 2, 5]$  no swap

$x = [1, 3, 4, \widehat{2}, 5]$  swap

$x = [1, 3, 2, \widehat{4}, 5]$  sweep done

new sweep

$x = [1, \widehat{3}, 2, 4, 5]$  no swap

$x = [1, 3, \widehat{2}, 4, 5]$  swap

$x = [1, 2, \widehat{3}, 4, 5]$  sweep done

last sweep

$x = [1, \widehat{2}, 3, 4, 5]$  no sweep

$x = [1, 2, \widehat{3}, 4, 5]$  sweep done

# Bubble sort properties

- This is the worst of all working algorithm!
- The execution time of this algorithm is  $\mathcal{O}(N^2)$
- Never use it in the real life!
- However it is very simple to program, and does not require extra memory for execution.

# Quick sort method

Much better yet simple algorithm

Let's discuss recursive realization

We will name our sorting function as `qsort` .

- choose a pivot point value
  - let's choose the pivot at the middle of the vector
  - `pivotIndex=floor(N/2)`
  - `pivotValue=x(pivotIndex)`
- create two vectors which hold lesser and larger than `pivotValue` elements of the input vector.
- now concatenate the result of  
`xs=[qsort (lesser), pivotValue, qsort (larger)]`
- done

# Quick sort summary

- usually fast
- typical execution time  $\mathcal{O}(N \log_2 N)$
- but it is not guaranteed
  - However for certain input vectors execution time could be as long as  $\mathcal{O}(N^2)$
