Midterm project

Problem (100 points total)

You are working for NASA. Your team is responsible to design a rocket which should lift off and after travel time $T_f = 50$ seconds in the gravity field of the Earth must reach a certain orbit with the final vertical velocity $v_f = 0$. Do not worry about horizontal velocity, it is another team responsibility.

Engineers provided you with an engine capable to provide to the rocket a time dependent lift acceleration in the form of $a(t) = 100 * \exp(-(\tanh(b * t) * b * t / 10)^2)$ (when other forces are disregarded) during time till a fuel line is cut off $T_c = 10$ seconds. The acceleration grows with time since rocket burns fuel and becomes lighter. However at time T_c no fuel is left and thus no lift force provided.

Assume that rocket starts from the planet Earth, treat the acceleration due to gravity as a constant $g = 9.8 \text{ m/s}^2$ (i.e. neglect gravitational force change). Disregard the air drag.

Task 1 (60 points): Your job is to find the proper value of coefficient b . Do not forget the units.

Task 2 (40 points): Plot velocity of the rocket as a function of time once the proper value of b is found.

Bonus is harder but it is within a reach!

Bonus (10 points): Plot the altitude of the rocket as a function of time. What is the altitude of the rocket at time T_f ?

Toy example - area of the pond

$$A_{pond} = \frac{N_{inside}}{N_{total}} A_{box}$$

where

$$A_{box} = (b_x - a_x)(b_y - a_y)$$

- Points must be **uniformly** and randomly distributed across the area.
- The smaller the enclosing box the better it is.

Naive Monte Carlo integration

$$\int_{a_x}^{b_x} f(x) dx = \frac{N_{inside}}{N_{total}} A_{box}$$

where

$$A_{box} = (b_x - a_x)(b_y)$$

- Points must be **uniformly** and randomly distributed across the area.
- The smaller the enclosing box the better it is. So $\max(f(x)) \rightarrow b_y$

Notes

Monte Carlo integration derived

Notice that if we choose a small stripe around the bin value x_b , then subset of points in that stripe gives an estimate for $f(x_b)$. Thus why bother spreading points around area?

Let's chose a uniform random distribution of points x_i inside $[a_x, b_x]$

$$\int_{a_x}^{b_x} f(x) dx \approx \frac{b_x - a_x}{N} \sum_{i=1}^N f(x_i)$$

Notes

Error estimate for Monte-Carlo method

It can be shown that error of the numerical integration (E) is given by the following expressions

Monte Carlo method

$$E = \mathcal{O} \left((b_x - a_x) \sqrt{\frac{\langle f^2 \rangle - \langle f \rangle^2}{N}} \right)$$

where

$$\langle f \rangle = \frac{1}{N} \sum_{i=1}^N f(x_i)$$

$$\langle f^2 \rangle = \frac{1}{N} \sum_{i=1}^N f^2(x_i)$$

Notes

Error estimate for other methods

Rectangle method

$$E = \mathcal{O} \left(\frac{(b_x - a_x)h}{2} f' \right) = \mathcal{O} \left(\frac{(b_x - a_x)^2}{2N} f' \right)$$

Trapezoidal method

$$E = \mathcal{O} \left(\frac{(b_x - a_x)h^2}{12} f'' \right) = \mathcal{O} \left(\frac{(b_x - a_x)^3}{12N^2} f'' \right)$$

Simpson method

$$E = \mathcal{O} \left(\frac{(b_x - a_x)h^4}{180} f^{(4)} \right) = \mathcal{O} \left(\frac{(b_x - a_x)^5}{180N^4} f^{(4)} \right)$$
