Notes

Bubble sort method

Someone gives us a vector of unsorted numbers. We want to obtain the vector sorted in ascending order.

- Assign the `IndexOfTheLastToCheck` to be the *index* of the vector end.
- Compare the 2 consequent elements starting from the beginning till we reach the `IndexOfTheLastToCheck`.
- If the left element is larger than the right one, we swap these 2 elements.
- Move to the next pair to the right, i.e., move to the item 2.
 - Notice that at the end of the sweep, the *index* of the last element to check holds the largest element.
 - So, the next sweep is shorter by one element.
 - I.e., the *index* of the last element to check should be decreased by 1.
- Decrease `IndexOfTheLastToCheck` by 1
- If `IndexOfTheLastToCheck > 1`, repeat from the second step.

```
x = [3, 1, 4, 5, 2]
the first sweep
x = [3, 1, 4, 5, 2] swap
x = [1, 3, 4, 5, 2] after swap
x = [1, 3, 4, 5, 2] no swap
x = [1, 3, 4, 5, 2] no swap
x = [1, 3, 4, 5, 2] swap
x = [1, 3, 4, 2, 5] sweep is done
new sweep
x = [1, 3, 4, 2, 5] no swap
x = [1, 3, 4, 2, 5] no swap
x = [1, 3, 4, 2, 5] swap
x = [1, 3, 2, 4, 5] sweep is done
new sweep
x = [1, 3, 2, 4, 5] no swap
x = [1, 3, 2, 4, 5] swap
x = [1, 2, 3, 4, 5] sweep is done
the last sweep
x = [1, 2, 3, 4, 5] no swap
x = [1, 2, 3, 4, 5] we are done
```

Notes

Bubble sort properties

- The execution time of this algorithm is $\mathcal{O}(N^2)$
- **This is the worst of all working algorithms!**
- **Never use it in real life!**
- However, it is quite intuitive and a very simple to program.
- It does not require extra memory during the execution.

Notes

Quick sort method

A much better, yet still simple algorithm. We will discuss the recursive realization. The name of our sorting function is `qsort`.

- Choose a pivot point value
 - let's choose the pivot at the middle of the vector
 - `pivotIndex=floor(N/2)`
 - `pivotValue=x(pivotIndex)`
- Create two vectors which hold the lesser and larger than `pivotValue` elements of the input vector.
- Now, concatenate the result as `xs=[qsort(lesser), pivotValue, qsort(larger)]`
- The sorting is done.

Notes

Quick sort summary

- It is very easy to implement.
- It is usually fast.
- A typical execution time is $\mathcal{O}(N \log_2 N)$.
- This is not guaranteed.
 - For certain input vectors the execution time could be as long as $\mathcal{O}(N^2)$.

Notes

Heap

The heap is a structure where a parent element is larger or equal to its children.

The top most element of a heap is called the root.

Notes

Heap sorting method

- 1 Fill the heap from the input vector elements.
 - 1 Take an element and place it at the bottom of the heap.
 - 2 Sift-up (bubble up) this element.
 - 3 Do the same with every following element.
- 2 Remove the root element, since it is the largest.
- 3 Rearrange the heap i.e. sift-down.
 - 1 Take the last bottom element.
 - 2 Place it at the root.
 - 3 Check if parent is larger than children.
 - 1 Find the largest child element.
 - 2 If the largest child is larger than parent, swap them and repeat the check in the sub heap of this child element.
- 4 Repeat step 2 until no elements are left in the heap.

The heap sorting complexity is $\mathcal{O}(N \log_2 N)$.

Notes

Filling (sift-up) the heap

Step 1

Place a new element at the bottom of the heap.

Notes

Filling (sift-up) the heap

Step 2

Check if the parent is larger than the child. If so, swap them and repeat the step 2.

Filling (sift-up) the heap

Step 2

Check if the parent is larger than the child. If so, swap them and repeat the step 2.

Filling (sift-up) the heap

Step 2

Check if the parent is larger than the child. If so, swap them and repeat the step 2.

Removing from the heap (sift-down) the heap

Step 1

Remove the root element.

Notes

Notes

Notes

Notes

Removing from the heap (sift-down) the heap

Step 2

Place the last element of the heap to the root position.

Removing from the heap (sift-down) the heap

Step 3

Check if the parent is smaller than the largest child. If so, swap and repeat the step 3, otherwise go to the step 1.

Removing from the heap (sift-down) the heap

Step 3

Check if the parent is smaller than the largest child. If so, swap and repeat the step 3, otherwise go to the step 1.

Removing from the heap (sift-down) the heap

The sequence repeats.

Step 1

Remove the root element

Notes

Notes

The vector heap representation

- Heap nodes are numbered consequently. These numbers represent the nodes positions in the vector (i.e., the linear array).
- Notice that the parent and its children have a very simple relationship
 - if a parent node index is i
 - the 1st child index is $2i$
 - the 2nd child index is $2i+1$
 - If we know a child index (i) then
 - the parent index is $\text{floor}(i/2)$

Matlab built-ins 'issorted' and 'sort'

An easy check if an array is sorted can be done with `issorted` which returns `true` or `false`.

```
>> x=[1,2,3];  
>> issorted(x)  
ans = 1
```

`issorted` checks only for the **ascending** order, for example

```
>> x=[3,2,1];  
>> issorted(x)  
ans = 0  
% Recall that '0' is equivalent of false in Matlab
```

Also, if you want to sort an array, the Matlab has the `sort` function to do it.

```
>> sort([5,3,2])  
ans = 2 3 5
```
