What is quantum optics

Classical/Geometrical optics

- light is a ray
- which propagates straight
- cannot explain diffraction and interference

Semiclassical optics

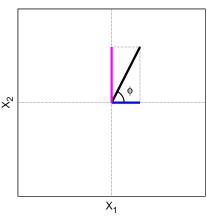

- light is a wave
- color (wavelength/frequency) is important
- amplitude (a) and phase are important, $E(t) = ae^{i(kz-\omega t)}$
- cannot explain residual measurements noise

Quantum optics

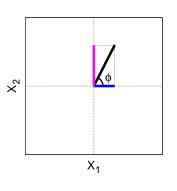

- light consists of photons: $N = a^{\dagger}a$
- detector measures quadratures: $X_1 = (a^{\dagger} + a)/2$ and $X_2 = i(a^{\dagger} a)/2$
- amplitude and phase cannot be measured precisely: $\Delta X_1 \Delta X_2 > 1/4$

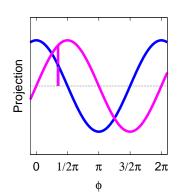

$$E(\phi) = |a|e^{-i\phi} = |a|\cos(\phi) + i|a|\sin(\phi) = X_1 + iX_2, \quad \phi = \omega t - kz$$

Detectors sense the real part of the field (X_1) but there is a way to see X_2 as well

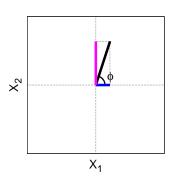

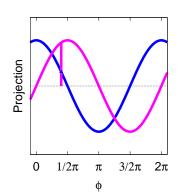

$$E(\phi) = |a|e^{-i\phi} = |a|\cos(\phi) + i|a|\sin(\phi) = X_1 + iX_2, \quad \phi = \omega t - kz$$

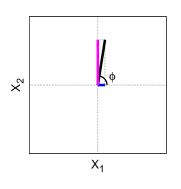

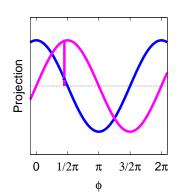

$$E(\phi) = |a|e^{-i\phi} = |a|\cos(\phi) + i|a|\sin(\phi) = X_1 + iX_2, \quad \phi = \omega t - kz$$

Transition from classical to quantum field

Classical analog

- Field amplitude a
- Field real part

$$X_1=(a^*+a)/2$$

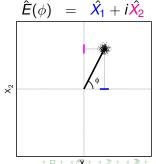

• Field imaginary part $X_2 = i(\hat{a}^* - a)/2$

$$E(\phi) = |a|e^{-i\phi} = X_1 + iX_2$$

Quantum approach

- Field operator â
- Amplitude quadrature $\hat{X_1} = (\hat{a}^{\dagger} + \hat{a})/2$
- Phase quadrature

• Phase quadrature
$$\hat{X}_2 = i(\hat{a}^{\dagger} - \hat{a})/2$$

Summary for crystal squeezing

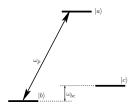

Pros

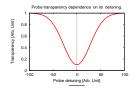

- mainstream: many different nonlinear crystals available
- so far the best squeezers
 - maximum squeezing value detected 11.5 dB at 1064 nm
 - Moritz Mehmet, Henning Vahlbruch, Nico Lastzka, Karsten Danzmann, and Roman Schnabel, "Observation of squeezed states with strong photon-number oscillations", Phys. Rev. A 81, 013814 (2010)
- well understood

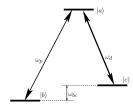

Cons

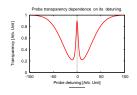

- crystals have limited transparency window
- thus squeezing is hard to generate at visible wavelength
 - at 795 nm only 4-6 dB squeezing is reported
- this limits applications of such squeezers for spectroscopy
