## Structure Functions

Unpolarized Cross Section:

$$\frac{d^2\sigma}{dxdQ^2} = \frac{8\pi\alpha^2 y}{Q^4} \left[\frac{y}{2}F_1 + \frac{\xi}{2xy}F_2\right]$$

Polarized Cross Section:

$$\frac{d^2\Delta\sigma}{dxdQ^2} = \frac{8\pi\alpha^2 y}{Q^4} \left[\cos\alpha\left\{\left(\xi + \frac{y}{2}\right)g_1 - \frac{\gamma y}{2}g_2\right\} - \sin\alpha\cos\phi\sqrt{\gamma\xi}\left\{\frac{y}{2}g_1 + g_2\right\}\right]$$

$$\begin{split} \alpha &= \text{polar angle of target spin wrt the beam axis} \\ \phi &= \text{azimuthal spin angle wrt the scattering plane} \\ \alpha &= 0^{\circ} \text{ (longitudinal); } \alpha = 90^{\circ}, \phi = 0^{\circ} \text{ (transverse).} \\ \gamma^2 &= 4M^2x^2/Q^2 = Q^2/\nu^2 \\ \xi &= 1 - y - \gamma y^2/4 \end{split}$$

Parton Model:  $F_1(x, Q^2) = \frac{1}{2} \sum_i e_i^2 (q^{\uparrow}(x) + q^{\downarrow}(x) + \bar{q}^{\uparrow}(x) + \bar{q}^{\downarrow}(x))$   $F_2(x, Q^2) = 2x F_1(x, Q^2)$   $g_1(x, Q^2) = \frac{1}{2} \sum_i e_i^2 (q^{\uparrow}(x) - q^{\downarrow}(x) + \bar{q}^{\uparrow}(x) - \bar{q}^{\downarrow}(x))$  $g_2(x, Q^2) = 0$ 

- violations.
- Our microscope, with resolution 1/Q, sees a bare quark clothed with the surrounding quarks and gluons.
- DGLAP equations describe QCD evolution of parton distributions:  $\partial q_i(x, Q^2) / \partial \ln Q^2 \sim \frac{\alpha_s(Q^2)}{2\pi} \int_x^1 \frac{dy}{y} P(y) \times q_i(\frac{x}{y}, Q^2)$  in which P(y) is the probability of a given parton splitting into two others.

- Both  $F_L$  and R are positive and get smaller slowly with  $Q^2$ .
- Resonances show up as bumps that move with x as  $Q^2$  increases.
- New global parametrization fits the  $Q^2$  dependence for each bin in W.
- DIS extrapolations do well on average in the resonance region (duality).
- The DIS R1998 fit to R does extremely well with the new data, whereas NNLO extrapolations fail.

- Old SLAC parametrization does well.
- NNLO QCD fit also generally agrees with the  $Q^2$  dependence when corrected for target-mass effects.
- Data at low  $Q^2$  are often plotted versus Nachtmann  $\xi = 2x/(1 + \sqrt{1 + 4M^2x^2/Q^2})$  to correct for targetmass. Because there are scaling violations at all  $Q^2$ , one might prefer to use  $(x, Q^2)$  consistently.

- Low-energy proton spectators from deuterium are hard to detect because of energy loss in the target.
- Slow spectators imply the neutron and proton are on average far apart (barely bound).
- Tagging slow protons from deuterium allows one to create a nearly free neutron target.
- Gaseous deuterium target; radial time projection chamber; gas electron multiplier (GEM) readout.

- Tagged structure functions corrected for nucleon motion show sharp peaks for elastic and resonances (right curve, expected results).
- Barely Offshell NUcleon Structure (BONUS) experiment will measure neutron structure functions without the usual proton contamination and smearing from deuterium.
- This method is especially useful at high x where model uncertainties dominate the extraction of  $F_2^n$ .
- This technique is easily extended to 12 GeV beams.

- CLAS has extended the measurements of  $g_1$  into the resonance region.
- The  $\Delta$  resonance, which moves upward in x with increasing  $Q^2$ , drives  $g_1$  negative.
- By comparison,  $g_1$  is always positive for DIS.

- Additional CLAS data have been taken at lower and higher energies for more complete kinematic coverage.
- For the 5.6 GeV data,  $g_1$  is positive.
- The  $\Delta$  drives the 1.6 GeV data negative.
- The newer data generally extend to lower x, and require less extrapolation when calculating moments.

- The model is a hybrid: DIS fits to data; resonance calculations using AO with helicity amplitudes mod-
- ified to fit data; smooth interpolation between the two regions.

- CLAS can only measure || spin configurations.
- Therefore,  $A_1 = \sigma_{TT} / \sigma_T$  cannot be separated from  $A_2 = \sigma_{LT} / \sigma_T$ .
- $\eta$  is generally small, so  $A_1$  dominates.

- Red curve: hybrid model
- Blue curve: estimate of  $\eta A_2$  from hybrid model.
- Plotted versus W, the data show resonance structure at fixed positions.

Hall A E94-010:  $g_1^{^{3}He}$  and  $g_2^{^{3}He}$ 

Polarized <sup>3</sup>He target enables measurement of  $\parallel$  and  $\perp$  asymmetries in the same experiment.

 $\begin{array}{l} g_2 \approx -g_1 \\ (\text{i.e. } \sigma_{LT} \approx 0) \end{array}$ 

## Hall A E97-103

- Jlab provides unprecedented precision for structure function measurements.
- Data must be used in global analyses that include all the world's data.
- There is room for more precise data here.

- Bjorken Sum Rule:  $\Gamma_1^p \Gamma_1^n = \frac{1}{6}g_A C_{ns}$
- $C_{ns}$  evolves with  $Q^2$ .
- At low  $Q^2$  where resonances dominate, the pQCD extrapolation fails.
- Data are presently being analyzed that will make a precise measure of the Bjorken sum below  $Q^2 \approx 1$  GeV<sup>2</sup>.

- Hall A will extend its polarized neutron structure function measurements to low  $Q^2$  by using a septum magnet to get down to 6° scattering angles (left graph).
- Hall B will extend its polarized proton structure function measurements to low  $Q^2$  by using a new smallangle Cherenkov counter (right graph).
- Together, these experiments will map out the approach to the Gerasimov-Drell-Hearn (GDH) limit.
- GDH extrapolation shows  $\Gamma_1 \rightarrow -\kappa^2 Q^2/8M^2$  as  $Q^2 \rightarrow 0$ .

## Conclusions

- Jlab results show exceptional precision and kinematic coverage for both unpolarized and polarized structure functions in the resonance region and beyond.
- Proper understanding in the framework of QCD requires an expansive data set for which the determination of moments of structure functions can be done without excessive extrapolation. This is now possible with JLab data.
- These high-quality data from JLab provide the framework for understanding the complex region between chiral and QCD perturbative descriptions.
- With the upgrade in energy and new techniques for measuring the neutron, JLab can effectively provide a complete set of data at low  $Q^2$  that ties directly to the world's DIS data.
